# Chemical Functional Group Reminder

Functional group	Class of compounds	Structural formula	Example	Ball-and-stick model
Hydroxyl -OH	Alcohols	$R-OH$	$\begin{array}{c} H & H \\   &   \\ H-C & -C-OH \\   &   \\ H & H \end{array}$ Ethanol	
Carbonyl -CHO	Aldehydes	$R-\overset{O}{\parallel}C-H$	$\begin{array}{c} H & O \\   &    \\ H-C & -C-H \\   & \\ H & \end{array}$ Acetaldehyde	
Carbonyl )CO	Ketones	$R-\overset{O}{\parallel}C-R$	$\begin{array}{c} H & O & H \\   &    &   \\ H-C & -C & -C-H \\   & &   \\ H & & H \end{array}$ Acetone	
Carboxyl -COOH	Carboxylic acids	$R-\overset{O}{\parallel}C-OH$	$\begin{array}{c} H & O \\   &    \\ H-C & -C-OH \\   & \\ H & \end{array}$ Acetic acid	
Amino -NH <sub>2</sub>	Amines	$R-NH_2$	$\begin{array}{c} H & H \\   &   \\ H-C & -N-H \\   &   \\ H & H \end{array}$ Methylamine	

PROTEINS

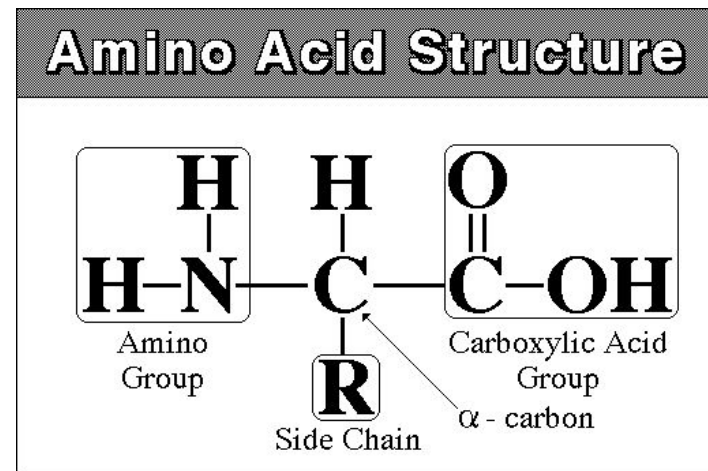

# Amino Acids

- Building blocks of Proteins
- Composed of two parts:
  - Backbone
  - Side-chain
- Biology employs 20 amino acids
  - Some can be modified for additional variability

# ***Biomolecules: Amino Acid***

- The general formula is
- $\text{H}_2\text{N}-\text{CHR}-\text{COOH}$ 
  - amino (  $\text{H}_2\text{N}-$  )
  - acid (  $-$  )
  - $-$ CHR $-$  group varies, and gives its identity to one of 20 amino acids used in proteins

# Proteins are made up of Amino Acids

- About half of the amino acids are "essential" meaning that they cannot be made by metabolic conversion from other molecules and thus need to be eaten
  - For the ten essential amino acids:
    - Threonine, Tryptophan, Valine, Arginine, Histidine, Lysine, Phenylalanine, Leucine, Isoleucine, Methionine
  - Remember this phrase:
    - **These Ten Valuable Amino Acids Have Long Preserved Life In Man**
  - This means our body has the ability to make the rest of the 20 amino acids from simpler building blocks

# Structures

# Side chains come in 4 “flavors”

AMINO ACID	SIDE CHAIN	AMINO ACID	SIDE CHAIN
Aspartic acid	negative	Alanine	nonpolar
Glutamic acid	negative	Glycine	nonpolar
Arginine	positive	Valine	nonpolar
Lysine	positive	Leucine	nonpolar
Histidine	positive	Isoleucine	nonpolar
Asparagine	uncharged polar	Proline	nonpolar
Glutamine	uncharged polar	Phenylalanine	nonpolar
Serine	uncharged polar	Methionine	nonpolar
Threonine	uncharged polar	Tryptophan	nonpolar
Tyrosine	uncharged polar	Cysteine	nonpolar

**POLAR AMINO ACIDS**  
(hydrophilic)

**NONPOLAR AMINO ACIDS**  
(hydrophobic)

# Amino Acids can sometimes be Modified in interesting ways

- Amino acids side groups may be further modified to have sugars, fats, other modifications
- Often these modifications are very important in changing the way the amino acid behaves

# Amino Acids are joined together using Peptide Bonds to make Proteins

- Biologists call this process translation, and it happens when a messenger RNA is “read” by a ribosome.
- Peptide bonds link amino acids together through  $-NH_2$  on one amino acid and  $-COOH$  on another

# Peptide Bond is Planar and rigid

\* The peptide plane consists of six atoms,  $C_{\alpha 1}$ , C, O, N, H,  $C_{\alpha 2}$

\* H-N-C<sub>α</sub> bond angle is 121°, not 109.5°.

# Properties of Peptide Bond

- Barrier to Rotation about C-N bond is 20 kcal
- Peptide bond is planar with C $\alpha$  groups typically trans to the peptide bond (better accommodate R groups)
- C and N are planar (2-D) and not able to rotate
- C $\alpha$  groups are tetrahedral (3-D) and able to rotate though some angles are unfavorable due to steric repulsion with other atoms.
- C $\alpha$  Naturally occurring amino acids are ALMOST exclusively the L stereoisomer.
